Abstract—This paper will explore the challenges of regression testing and monitoring of large scale systems such as NCSAs Blue Waters. Our goal was to come up with an automated solution for running user-level regression tests to evaluate system usability and performance. Another requirement was to find an automated solution for running a suite of test jobs that reveal the system health after upgrades and outages before returning the system to service. We evaluated test frameworks such as Inca [1] and Jenkins [2]. Jenkins was chosen for its versatility, large user base, and multitude of plugins including plotting test results over time. We utilize these plots to track trends and alert us to system-level issues before they are reported by our partners (users). Not only does Jenkins have the ability to store historical data but it can also send customized notifications (e.g. send email or text pages) based on the result of a test. Some of the requirements we had include two-factor authentication to access Jenkins GUI with privileges to execute tests and account management through LDAP. In this paper we describe our implementation of these requirements to ensure a secure and usable deployment of a Jenkins instance.

Our Jenkins instance was deployed on a vSphere managed VM running Centos 6.8. Security was of the highest concern since Jenkins has the ability to execute commands on our login nodes. Jenkins is set to log in as a standard user account with password-less access (commands to the login nodes can be input via Jenkins GUI) using ssh keys scoped to the VM. The VM (bwjenkins) was closely vetted by our security team on our test and development system (TDS) before it was allowed access to Blue Waters. Iptables was used to lock bwjenkins down to a small internal ip space to ensure the highest security. An anonymous user account was enabled with read-only access to view current and historical test results. During a test, Jenkins downloads software, builds the software, submits a job, awaits completion, gathers and plots the results or returns error information during a failure. These are full end to end functionality tests of the programming environment, queueing system, license servers and they provide historical metrics to quickly detect regressions.

In this paper we describe in detail our challenges and experiences in deploying Jenkins as a user-level system-wide regression testing and monitoring framework for Blue Waters. We will also show some application-based system-level tests we have implemented in Jenkins and share results of those tests. The deployment of Jenkins allows us to monitor and detect issues as early as possible from the perspective of a user on Blue Waters, eventually providing a more efficient service for better user experience.

ture

I. MOTIVATION

Our goal was to come up with an automated solution for running user-level regression tests to evaluate system usability and performance. Another requirement was to find an automated solution for running a suite of test jobs that reveal the system health after upgrades and outages before returning the system to service.

II. JENKINS CONFIGURATION

A. Introduction to Jenkins

Jenkins [2] is a self-contained, open source automation server which can be used to automate all sorts of tasks such as building, testing, and deploying software. Jenkins can be installed through native system packages, Docker, or even run standalone by any machine with the Java Runtime Environment installed. To install from rpm as root: `wget -O /etc/yum.repos.d/jenkins.repo http://pkg.jenkins-ci.org/redhat/jenkins.repo rpm --import https://jenkins-ci.org/redhat/jenkins-ci.org.key yum install jenkins`

B. Master-Node Configuration

We added a standard user account to our cluster that will execute the Jenkins tests. Unique ssh keys were generated on the Jenkins Server for accessing the user account on production and test environments. The keys on the server are located in Jenkins home directory (`/var/lib/jenkins/.ssh`). Using the GUI management console, the keyfile location and passphrase was entered under Manage Jenkins, Configure System, SSH remote hosts section. A unique SSH site is configured for our TDS, production and development login nodes.

C. Accessing Login Nodes

The ssh public key generated on Jenkins Server was deployed in the login node user account. The login node `sshd_config` was modified to allow Public Key Authentication from the Jenkins Server IP.

III. AUTHENTICATION AND AUTHORIZATION

A. Security Considerations

Enabling Jenkins access to Blue Waters posed some unique security hurdles that we had to overcome. Blue Waters is an OTP only restricted access system. Jenkins has the ability to execute user-level commands on our login nodes. Jenkins has some unfortunate default settings. The access control is set to "Jenkins' own user database," and the "Allow users to sign up" option is enabled, so if you don't have an account, you can create one by providing your name, e-mail and a password. Additionally, there's an authorization option enabled which says "Logged-in users can do anything." So, once you complete the sign up form, you have full admin access to the system. This required us initially to test the deployment with our test and development (TDS) CRAY. This resulted in the following requirements. Restricted OTP access to the physical system that will host Jenkins. In addition, OTP only access to the Jenkins GUI command console that must be contained within our IP space. The Jenkins GUI will also restrict the command console access to our Blue Waters LDAP server.

B. Configuration Choices

Jenkins instance was deployed on a vSphere managed VM running Centos 6.8. The VM allows restricted host-based ssh access from two secure OTP only administrative systems. The Jenkins GUI presented additional challenges. The Jenkins GUI is configured to log in as a standard user account with pass-wordless access (commands to the login nodes can be input via Jenkins GUI) using ssh keys scoped to the VM. We restricting access to the physical VM (bwjenkins) and the Jenkins GUI utilizing iptables, SSL and OTP. A reverse proxy was used to run Jenkins behind apache/http with SSL for access to the administrative console. All the configuration is in /etc/httpd/conf.d/ssl.conf. Anonymous access to the Jenkins GUI was allowed for limited read only view of test status and historical plots. The Anonymous access view is not restricted.

(config file snippets below)

```
/etc/ssh/sshd_config:
Match Host bwbh1.ncsa.illinois.edu,
bwbh2.ncsa.illinois.edu
HostbasedAuthentication yes
```

```
/etc/sysconfig/iptables:
-A INPUT -s 141.142.0.0/16 -m state --state NEW -m tcp
-p tcp --dport 22 -j ACCEPT
-A INPUT -s 172.16.0.0/15 -m state --state NEW -m tcp
-p tcp --dport 22 -j ACCEPT *delete maybe*
-A INPUT -m state --state NEW -m tcp -p tcp --dport 80
-j ACCEPT
-A INPUT -s 141.142.0.0/16 -m state --state NEW -m tcp
-p tcp --dport 443 -j ACCEPT
```

```
/etc/httpd/conf.d/ssl.conf:
Listen 443
```

```
<VirtualHost _default_:443>

VI. USE CASES

A. IOR Lustre scratch test

We created Jenkins tests to periodically run the IOR MPI parallel i/o benchmark at modest scale and validate filesystem functionality and performance for the scratch filesystem. The test is scaled to provide representative performance numbers for a typical small application while not creating performance issues with other jobs or the larger filesystem. One of our best practices is to provide a management level summary description for casual jenkins users who want to

view the tests but do not need to understand the full Jenkins configuration and execution details.

Project IOR-bluewaters

IOR filesystem benchmark Scheduling frequency 6h , nodes=16;ppn=7;walltime=00:10:00

This is a small benchmark that matches the one on jyc: #PBS -l nodes=16;ppn=7;walltime=00:10:00 , using a stripe8/ directory created via "fs setstripe -c 8 stripe8" . Performance should meet or exceed jyc's performance on average (jyc is typically dedicated while bluewaters is highly shared). The idea is to have a baseline of performance without being overly intrusive on the batch system or filesystem.

bwjenkins has been added to the acl for ~arnoldfor and as a secondary objective, the ior binary is rebuilt for each trial -- testing the compilers and environment on blue waters.

Tests: automake, autocount, and default build environment, Lustre striping and throughput for a small job, scratch

[edit description](#)

[Disable Project](#)

Figure 5: IOR description in jenkins

Where possible, tests build from source and exercise multiple user-facing system components such as: git for external connectivity and modules to test defaults in the environment. Where scripts on the remote SSH site are used, they are echoed and/or displayed with "cat -n" to make console output verbose and easy to debug in case of errors.

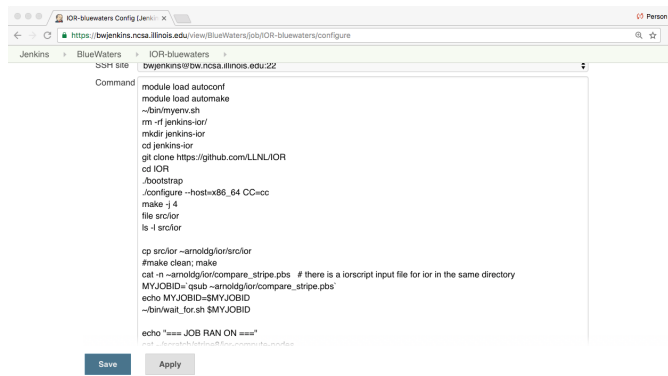

Figure 6: IOR configuration sample

The IOR test is set to run as scheduled by Jenkins with a best-effort through our batch system. The test synchronously blocks such that the next test will not start until the previous one has completed. We employ a watchdog script to monitor the batch queue and keep the test active until the system marks it as finished. This has the side effect of making the minimum test time an integer multiple of the sleep time in the watchdog script. This may be adjusted to fit individual site needs.

Listing 1: pbs/torque watchdog script

```
#!/bin/bash
echo "===_RUNNING_$0_==="
if [ $# -lt 1 ]
then
    echo "$0: missing argument for _jobid"
    exit 1
fi
while true
do
```

```
MYQSTAT=`qstat $1`
if test "$MYQSTAT" = ""
then
    echo $1 finished
    exit
else
    DATE=`date`
    echo "$DATE: waiting for $1 to finish"
fi
sleep 5m
done
```

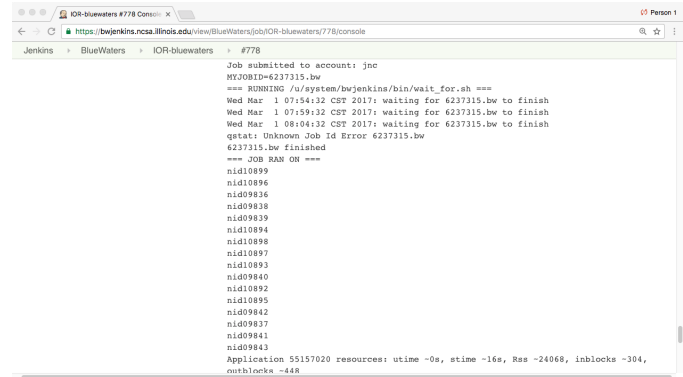

Figure 7: IOR watchdog console output

For tests that produce an interesting performance metric like IOR, we save that output to the file format expected by Jenkins and use plotting feature to produce plots.

Listing 2: sample YVALUE output file

```
bwjenkins$ cat myiorREADnumber.dat
YVALUE=8352.71
```

Figure 8: IOR plot view

A plot like this helps us with performance baselines and we can quickly react to changes in the software environment or filesystem configuration that adversely impact performance.

B. *mdtest* Lustre tests

The mdtest metadata test is run on the home and scratch filesystems to validate metadata server performance. The IOR and mdtest user-facing tests complement the fine-grained detail we are able to glean from the backed system-side counters in our OVIS database where we record details about individual server metrics and network traffic on the Cray Gemini fabric.

Figure 9: mdtest plot view

An additional best practice is to enable E-mail Notifications to the test author and/or other interested parties. Setting notifications for unstable builds will trigger an E-mail every time the test state changes (from successful to failing and again when back to successful).

E-mail Notification

Recipients

arnoldg@ncsa.illinois.edu

Whitespace-separated list of recipient addresses. May reference build parameters like \$PARAN. E-mail will be sent when a build fails, becomes unstable or returns to stable.

☒ Send e-mail for every unstable build

☐ Send separate e-mails to individuals who broke the build

Add post-build action

Delete

Figure 10: mdtest email configuration

C. filesystem dashboard

Our Jenkins instance is a source of information for a filesystem dashboard display we maintain in our wiki. The "http://" urls for the plot images are shown on the dashboard and provide a recent-time display of filesystem metrics from a user point of view. We add a Jenkins test to track response time of /bin/lis on the login nodes—a reasonable metric of metadata server health and also the most common problem reported by users when we are having filesystem issues.

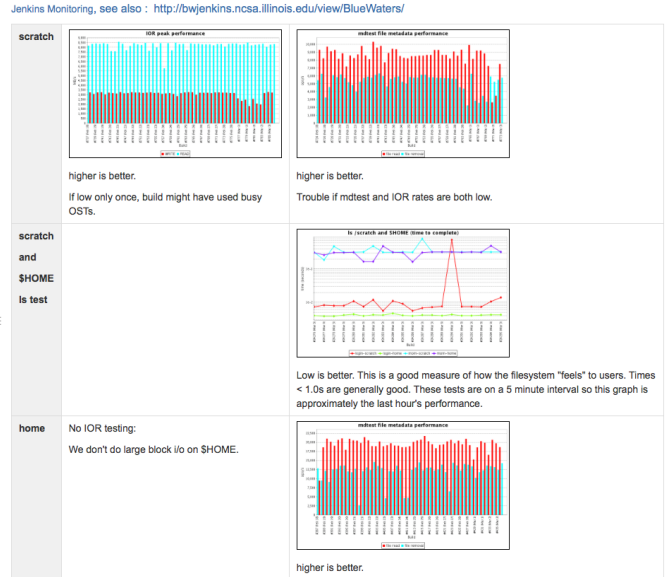

Figure 11: filesystem dashboard displaying multiple Jenkins plots

D. special projects

The initial display tabs in our Jenkins instance are used to group tests and we add tabs for special projects. For example we clone existing tests for evaluating a new software stack on our test login node. Our test rack has a separate set of tests from our production system and is used as our Jenkins development mule. The sustained petascale performance benchmarks are in their own tab because they run at scale and are only run on-demand by staff (not scheduled by Jenkins).

The "All" category contains all tests, both those assigned to another tab (in production) and tests currently in development.
